WCOM125/ COMP125 Week 1

COMP115/ WCOM115 Revision

April 27, 2017

1. What is the value of `result` when the following code is executed? Show your working using a logic table.

```
int result = 3;
for(int i=1; i <= 20; i+=3) {
        if(i % 4 == 0) {
                result *= 2;
        }
        else {
                result--;
        }
}
```

2. Write a piece of code that adds the first 100 positive integers (1 to 100) and stores the result in a variable `total`. You must use a loop in order to achieve this.

3. What is the value of `result` when the following code is executed? Show your working using a logic table.

```
int total = 0;
for(int i=1; i <= 10; i+=3) {
   for(int k=1; k <= i; k+=3) {
      result++;
   }
}
```

4. What is the value of `result` when the following code is executed? Show your working using a memory diagram.

```
boolean foo(int n) {
        if(n > 5 && n < 10) {
                return true;
        }
        else {
                return false;
        }
}

void setup() {
        int a = 12;
        boolean result = foo(a);
}
```

5. Define a function that when passed an integer, returns `true` if it's even (divisible by 2) and `false` otherwise.

6. What is the value of `result` when the following code is executed?

```
int bar(int a, int b) {
        if(a > b)
                return a;
        else
                return b;
}

void setup() {
        int result = bar(bar(4,2), bar(3,6));
}
```

7. Define a function that when passed an integer (call it `num` in the scope of the function call), returns the sum of the first `num` positive integers. You may assume `num` > 0. For example, if `num = 4`, function should return 10 (1+2+3+4 = 10).

8. What changes must you make to the function `sum` defined above if the assumption (`num` > 0) is no longer valid. What value do you think should be returned for `num` ≤ 0

9. Define a function that when passed two integers (call them `x, n` in the scope of the function call), returns the x^n (`x * x * x ... n times`). You may assume `n` > 0. For example, if `x = 2, n = 4`, function should return 16 ($2^4 = 2 * 2 * 2 * 2 = 16$).

10. Create an array that holds 500 integers. Using a loop, populate the array, such that,

    - the first item is 5
    - the second item is 7
    - the third item is 9
    - the fourth item is 11
    - and so on

11. Create an array that holds 100 real numbers. Using a loop, populate the array, such that,

    - the first item is 7.5
    - the second item is 7.45
    - the third item is 7.40
    - the fourth item is 7.35
    - and so on

12. Consider the following function definition,

```
1 float square(float n) {
2         return n*n;
3 }
```

Write one or two statements that sit inside the `setup()` function that calls the function `square` to compute 5^2, and stores the returned value in a variable `result`. You must declare the variable `result` to an appropriate data type.

13. Define a function `total` that when passed an integer array, returns the sum of all the items in the array. Return 0 if the array is `null`

14. What changes must you make to the function `total` defined above if you want to add **only the positive items**?

15. What changes must you make to the function `total` defined above if you want to add **only the items in a specific range**. Say items that lie between:

    - 1 and 6, or,
    - 50 and 100

16. Define a function `highest` that when passed an integer array, returns the highest value in the array. Return 0 if the array is`null` or if the array is empty.

17. What changes must you make to the function `highest` defined above if you want to return the **smallest item**.

18. Define a function `highestIndex` that when passed an integer array, returns the **index of** the highest value in the array. Return -1 if the array is`null` or if the array is empty.

19. Which function is more powerful - `highest`, or `highestIndex`?

20. What changes must you make to the function `highestIndex` defined above if you want to return the **index of the smallest item**.

21. What changes must you make to the function `highest` defined above if you want to return the highest value **starting from a specific index**. For example, if `a = {40, 80, 30, 50, 70, 20}`, and the index starting at which we should look is 3 (note that a[3] is 50), the function returns 70

22. What changes must you make to the function `highest` defined above if you want to return the **index of** the highest value **starting from a specific index**. For example, if `a = {40, 80, 30, 50, 70, 20}`, and the index starting at which we should look is 3 (note that a[3] is 50), the function returns 4 (item at index 4 is the highest starting at index 3).

23. Define a function `identical` that when passed two integer arrays, returns `true` if they are identical to each other, `false` otherwise (or if either of the arrays is `null`).

24. **(advanced)** Define a function `withoutFirstDigit` that when passed an integer n, returns the number without the first digit. You may assume that m is more than 0. For example, if $m = 7129$, function returns 129.

25. Draw the memory diagram that captures the transactions when the following code executes.

```
int[] a = {1, 7, 2};
int[] b = a;
int[] c = new int[a.length];
for(int i=0; i < a.length; i++) {
        c[i] = a[i];
}
```
